

EE-559 – Deep learning

5.4. L_2 and L_1 penalties

François Fleuret

<https://fleuret.org/ee559/>

Mar 16, 2020

We have motivated the use of a loss with a Bayesian formulation combining the probability of the data given the model and the probability of the model

$$\log \mu_W(w \mid \mathcal{D} = \mathbf{d}) = \log \mu_{\mathcal{D}}(\mathbf{d} \mid W = w) + \log \mu_W(w) - \log Z.$$

We have motivated the use of a loss with a Bayesian formulation combining the probability of the data given the model and the probability of the model

$$\log \mu_W(w \mid \mathcal{D} = \mathbf{d}) = \log \mu_{\mathcal{D}}(\mathbf{d} \mid W = w) + \log \mu_W(w) - \log Z.$$

If μ_W is a Gaussian density with a covariance matrix proportional to the identity, the log-prior $\log \mu_W(w)$ results in a quadratic penalty

$$\lambda \|w\|_2^2.$$

We have motivated the use of a loss with a Bayesian formulation combining the probability of the data given the model and the probability of the model

$$\log \mu_W(w \mid \mathcal{D} = \mathbf{d}) = \log \mu_{\mathcal{D}}(\mathbf{d} \mid W = w) + \log \mu_W(w) - \log Z.$$

If μ_W is a Gaussian density with a covariance matrix proportional to the identity, the log-prior $\log \mu_W(w)$ results in a quadratic penalty

$$\lambda \|w\|_2^2.$$

Since this penalty is convex, its sum with a convex functional is convex.

This is called the L_2 regularization, or “weight decay” in the artificial neural network community.

Increasing the λ parameter moves the optimal closer to 0, and away from the optimal for the loss alone.

Since the derivative of $\|x\|_2^2$ is zero at zero, the optimal will never move there if it was not already there.

$$(x - 1)^2 + \frac{1}{6}(x - 1)^3$$

Increasing the λ parameter moves the optimal closer to 0, and away from the optimal for the loss alone.

Since the derivative of $\|x\|_2^2$ is zero at zero, the optimal will never move there if it was not already there.

$$(x - 1)^2 + \frac{1}{6}(x - 1)^3 + x^2$$

Increasing the λ parameter moves the optimal closer to 0, and away from the optimal for the loss alone.

Since the derivative of $\|x\|_2^2$ is zero at zero, the optimal will never move there if it was not already there.

$$(x - 1)^2 + \frac{1}{6}(x - 1)^3 + 2x^2$$

Increasing the λ parameter moves the optimal closer to 0, and away from the optimal for the loss alone.

Since the derivative of $\|x\|_2^2$ is zero at zero, the optimal will never move there if it was not already there.

$$(x - 1)^2 + \frac{1}{6}(x - 1)^3 + 3x^2$$

Increasing the λ parameter moves the optimal closer to 0, and away from the optimal for the loss alone.

Since the derivative of $\|x\|_2^2$ is zero at zero, the optimal will never move there if it was not already there.

$$(x - 1)^2 + \frac{1}{6}(x - 1)^3 + 4x^2$$

Convnet trained on MNIST with 1,000 samples and a L_2 penalty.

We can apply the exact same scheme with a Laplace prior

$$\begin{aligned}\mu(w) &= \frac{1}{(2b)^D} \exp\left(-\frac{\|w\|_1}{b}\right) \\ &= \frac{1}{(2b)^D} \exp\left(-\frac{1}{b} \sum_{d=1}^D |w_d|\right),\end{aligned}$$

We can apply the exact same scheme with a Laplace prior

$$\begin{aligned}\mu(w) &= \frac{1}{(2b)^D} \exp\left(-\frac{\|w\|_1}{b}\right) \\ &= \frac{1}{(2b)^D} \exp\left(-\frac{1}{b} \sum_{d=1}^D |w_d|\right),\end{aligned}$$

which results in a penalty term of the form

$$\lambda \|w\|_1.$$

This is the L_1 regularization.

We can apply the exact same scheme with a Laplace prior

$$\begin{aligned}\mu(w) &= \frac{1}{(2b)^D} \exp\left(-\frac{\|w\|_1}{b}\right) \\ &= \frac{1}{(2b)^D} \exp\left(-\frac{1}{b} \sum_{d=1}^D |w_d|\right),\end{aligned}$$

which results in a penalty term of the form

$$\lambda \|w\|_1.$$

This is the L_1 regularization. As for the L_2 , this penalty is convex, and its sum with a convex functional is convex.

An important property of the L_1 penalty is that, if \mathcal{L} is convex, and

$$w^* = \underset{w}{\operatorname{argmin}} \mathcal{L}(w) + \lambda \|w\|_1$$

then

$$\forall d, \left| \frac{\partial \mathcal{L}}{\partial w_d}(w^*) \right| < \lambda \Rightarrow w_d^* = 0.$$

In practice it means that this penalty pushes some of the variables to zero, but contrary to the L_2 penalty they actually move and remain there.

The λ parameter controls the sparsity of the solution.

With the L_1 penalty, the update rule becomes

$$w_{t+1} = w_t - \eta (g_t + \lambda \text{sign}(w_t)),$$

With the L_1 penalty, the update rule becomes

$$w_{t+1} = w_t - \eta (g_t + \lambda \text{sign}(w_t)),$$

where sign is applied per-component. This is almost identical to

$$\begin{aligned} w'_t &= w_t - \eta g_t \\ w_{t+1} &= w'_t - \eta \lambda \text{sign}(w'_t). \end{aligned}$$

With the L_1 penalty, the update rule becomes

$$w_{t+1} = w_t - \eta (g_t + \lambda \text{sign}(w_t)),$$

where sign is applied per-component. This is almost identical to

$$\begin{aligned} w'_t &= w_t - \eta g_t \\ w_{t+1} &= w'_t - \eta \lambda \text{sign}(w'_t). \end{aligned}$$

This update may overshoot, and result in a component of w'_t strictly on one side of 0, while the same component in w_{t+1} is strictly on the other.

With the L_1 penalty, the update rule becomes

$$w_{t+1} = w_t - \eta (g_t + \lambda \text{sign}(w_t)),$$

where sign is applied per-component. This is almost identical to

$$\begin{aligned} w'_t &= w_t - \eta g_t \\ w_{t+1} &= w'_t - \eta \lambda \text{sign}(w'_t). \end{aligned}$$

This update may overshoot, and result in a component of w'_t strictly on one side of 0, while the same component in w_{t+1} is strictly on the other.

While this is not a problem in principle, since w_t will fluctuate around zero, it can be an issue if the zeroed weights are handled in a specific manner (e.g. sparse coding to reduce memory footprint or computation).

The **proximal operator** takes care of preventing parameters from “crossing zero”, by adapting λ when it is too large

$$w'_t = w_t - \eta g_t$$
$$w_{t+1} = w'_t - \eta \min(\lambda, |w'_t|) \odot \text{sign}(w'_t).$$

where \min is component-wise, and \odot is the Hadamard component-wise product.

Increasing the λ parameter moves the optimal closer to 0, and away from the optimal for the loss without penalty.

$$(x - 1)^2 + \frac{1}{6}(x - 1)^3$$

Increasing the λ parameter moves the optimal closer to 0, and away from the optimal for the loss without penalty.

$$(x - 1)^2 + \frac{1}{6}(x - 1)^3 + \frac{1}{2}|x|$$

Increasing the λ parameter moves the optimal closer to 0, and away from the optimal for the loss without penalty.

$$(x - 1)^2 + \frac{1}{6}(x - 1)^3 + |x|$$

Increasing the λ parameter moves the optimal closer to 0, and away from the optimal for the loss without penalty.

$$(x - 1)^2 + \frac{1}{6}(x - 1)^3 + \frac{3}{2}|x|$$

Increasing the λ parameter moves the optimal closer to 0, and away from the optimal for the loss without penalty.

$$(x - 1)^2 + \frac{1}{6}(x - 1)^3 + 2|x|$$

Convnet trained on MNIST with 1,000 samples and a L_1 penalty.

Penalties on the weights may be useful when dealing with small models and small data-sets and are still standard when data is scarce.

While they have a limited impact for large-scale deep learning, they may still provide the little push needed to beat baselines.

The end
