Deep learning

10.1. Auto-regression

François Fleuret

https://fleuret.org/dlc/

Jan 1, 2021
Auto-regression methods model components of a signal serially, each one conditionally to the ones already modeled.

They rely on the chain rule from probability theory: given $X_1, \ldots, X_T$ random variables, we have

$$
\forall x_1, \ldots, x_T, \quad P(X_1 = x_1, \ldots, X_T = x_T) =
$$

$$
P(X_1 = x_1) P(X_2 = x_2 \mid X_1 = x_1) \ldots P(X_T = x_T \mid X_1 = x_1, \ldots, X_{T-1} = x_{T-1}).
$$
Auto-regression methods model components of a signal serially, each one conditionally to the ones already modeled.

They rely on the chain rule from probability theory: given $X_1, \ldots, X_T$ random variables, we have

$$\forall x_1, \ldots, x_T, \quad P(X_1 = x_1, \ldots, X_T = x_T) = \left. P(X_T = x_T \mid X_1 = x_1, \ldots, X_{T-1} = x_{T-1}) \right| \left. P(X_{T-1} = x_{T-1} \mid X_1 = x_1, \ldots, X_{T-2} = x_{T-2}) \right| \ldots \left. P(X_1 = x_1) \right| \left. x_1 \right) .$$

Deep neural networks are a fitting class of models for such conditional densities when dealing with large dimension signal (Larochelle and Murray, 2011).
Given a sequence of random variables $X_1, \ldots, X_T$ on $\mathbb{R}$, we can represent a conditioning event of the form

$$X_{t(1)} = x_1, \ldots, X_{t(N)} = x_N$$

with two tensors of dimension $T$: the first a Boolean mask stating which variables are conditioned, and the second the actual conditioning values.

*E.g.*, with $T = 5$

<table>

In what follows, we will consider only finite distributions over $C$ real values, hence we can model a conditional distribution with a mapping

$$f : \{0, 1\}^Q \times \mathbb{R}^Q \rightarrow \mathbb{R}^C,$$

where the $C$ output values can be either probabilities, or as we will prefer, logits.
In what follows, we will consider only finite distributions over $C$ real values, hence we can model a conditional distribution with a mapping

$$f : \{0, 1\}^Q \times \mathbb{R}^Q \rightarrow \mathbb{R}^C,$$

where the $C$ output values can be either probabilities, or as we will prefer, logits.

This can be generalized beyond categorical distributions by mapping to parameters of any distribution on $\mathbb{R}$.
Given such a model and a sampling procedure \textit{sample}, the generative process for a full sequence is

\begin{align*}
x_1 & \leftarrow \text{sample} \left( f(\{\}) \right) \\
x_2 & \leftarrow \text{sample} \left( f(\{X_1 = x_1\}) \right) \\
x_3 & \leftarrow \text{sample} \left( f(\{X_1 = x_1, X_2 = x_2\}) \right) \\
& \ldots \\
x_T & \leftarrow \text{sample} \left( f(\{X_1 = x_1, X_2 = x_2, \ldots, X_{T-1} = x_{T-1}\}) \right)
\end{align*}
With $C = 3$ and $T = 5$:

\end{align*}
$$
The package `torch.distributions` provides the necessary tools to sample from a variety of distributions.

```python
>>> l = torch.tensor([ log(0.8), log(0.1), log(0.1) ])
>>> dist = torch.distributions.categorical.Categorical(logits = l)
>>> s = dist.sample((10000,))
>>> (s.view(-1, 1) == torch.arange(3).view(1, -1)).float().mean(0)
tensor([0.8037, 0.0988, 0.0975])
```

Sampling can also be done in batch

```python
>>> l = torch.tensor([ [ log(0.90), log(0.10) ],
...                     [ log(0.50), log(0.50) ],
...                     [ log(0.25), log(0.75) ],
...                     [ log(0.01), log(0.99) ]])
>>> dist = torch.distributions.categorical.Categorical(logits = l)
>>> dist.sample((8,))
tensor([[0, 1, 1, 1],
        [0, 1, 1, 1],
        [0, 0, 1, 1],
        [0, 1, 0, 1],
        [1, 0, 1, 1],
        [0, 1, 1, 1],
        [0, 1, 1, 1],
        [0, 0, 1, 1]])
```
The package `torch.distributions` provides the necessary tools to sample from a variety of distributions.

```python
def demo_logit_theta():
    l = torch.tensor([log(0.8), log(0.1), log(0.1)])
    dist = torch.distributions.categorical.Categorical(logits=l)
    s = dist.sample(10000)
    return (s.view(-1, 1) == torch.arange(3).view(1, -1)).float().mean()

demo_logit_theta().item()
```

Sampling can also be done in batch

```python
>>> l = torch.tensor([[log(0.90), log(0.10)],
                    [log(0.50), log(0.50)],
                    [log(0.25), log(0.75)],
                    [log(0.01), log(0.99)]])
>>> dist = torch.distributions.categorical.Categorical(logits=l)
>>> dist.sample((8,))
tensor([[0, 1, 1, 1],
        [0, 1, 1, 1],
        [0, 0, 1, 1],
        [0, 1, 0, 1],
        [1, 0, 1, 1],
        [0, 1, 1, 1],
        [0, 1, 1, 1],
        [0, 0, 1, 1]])
```
With a finite distribution and the output values interpreted as logits, training consists of maximizing the likelihood of the training samples, hence minimizing

$$\mathcal{L}(f) = - \sum_n \sum_t \log \hat{p}(X_t = x_{n,t} \mid X_1 = x_{n,1}, \ldots, X_{t-1} = x_{n,t-1})$$

$$= \sum_n \sum_t \ell\left(f((1, \ldots, 1, 0, \ldots, 0), (x_{n,1}, \ldots, x_{n,t-1}, 0, \ldots, 0)), x_{n,t}\right)$$

where $\ell$ is the cross-entropy.
In practice, for each batch, we sample an index to predict in each at random, from which we build the masks, conditioning values, and target values.

Training sequences

```
[[ 3, 1, 8, 1, 0, 3 ],
 [ 2, 3, 0, 9, 6, 5 ],
 [ 7, 1, 5, 7, 3, 1 ],
 [ 6, 0, 2, 3, 1, 9 ]]```
In practice, for each batch, we sample an index to predict in each at random, from which we build the masks, conditioning values, and target values.

Training sequences

[[ 3, 1, 8, 1, 0, 3 ],
 [ 2, 3, 0, 9, 6, 5 ],
 [ 7, 1, 5, 7, 3, 1 ],
 [ 6, 0, 2, 3, 1, 9 ]]
In practice, for each batch, we sample an index to predict in each at random, from which we build the masks, conditioning values, and target values.

Training sequences

\[
\begin{align*}
[3, 1, 8, 1, 0, 3], \\
[2, 3, 0, 9, 6, 5], \\
[7, 1, 5, 7, 3, 1], \\
[6, 0, 2, 3, 1, 9] \\
\end{align*}
\]

Input

\[
\begin{align*}
[1, 1, 0, 0, 0, 0], \\
[1, 1, 1, 1, 1, 0], \\
[1, 1, 1, 0, 0, 0], \\
[1, 0, 0, 0, 0, 0] \\
\end{align*}
\]

Masks

\[
\begin{align*}
[3, 1, 0, 0, 0, 0], \\
[2, 3, 0, 9, 6, 0], \\
[7, 1, 5, 0, 0, 0], \\
[6, 0, 0, 0, 0, 0] \\
\end{align*}
\]

Values
In practice, for each batch, we sample an index to predict in each at random, from which we build the masks, conditioning values, and target values.

```
[ 3, 1, 8, 1, 0, 3 ],
[ 2, 3, 0, 9, 6, 5 ],
[ 7, 1, 5, 7, 3, 1 ],
[ 6, 0, 2, 3, 1, 9 ]
```

Training sequences
```
[ 1, 1, 0, 0, 0, 0 ],
[ 1, 1, 1, 1, 1, 0 ],
[ 1, 1, 1, 0, 0, 0 ],
[ 1, 0, 0, 0, 0, 0 ]
```

Input
```
[ [ 1, 1, 0, 0, 0, 0 ],
  [ 1, 1, 1, 1, 1, 0 ],
  [ 1, 1, 1, 0, 0, 0 ],
  [ 1, 0, 0, 0, 0, 0 ] ]
```

Masks
```
[ [ 3, 1, 0, 0, 0, 0 ],
  [ 2, 3, 0, 9, 6, 0 ],
  [ 7, 1, 5, 0, 0, 0 ],
  [ 6, 0, 0, 0, 0, 0 ] ]
```

Values
```
[ 8,
  5,
  7,
  0 ]
```

Target
Consider a toy problem, where sequences from \( \{1, \ldots, C\}^T \) are split in two at a random position, and are linear in both parts, with slopes \( \sim U([-1, 1]) \).

Values are re-centered and discretized into \( 2T \) values.

Model

class Net(nn.Module):
    def __init__(self, nb_values):
        super().__init__()

        self.features = nn.Sequential(
            nn.Conv1d(2, 32, kernel_size = 5),
            nn.ReLU(),
            nn.MaxPool1d(2),
            nn.Conv1d(32, 64, kernel_size = 5),
            nn.ReLU(),
            nn.MaxPool1d(2),
            nn.ReLU(),
        )

        self.fc = nn.Sequential(
            nn.Linear(320, 200),
            nn.ReLU(),
            nn.Linear(200, nb_values)
        )

    def forward(self, x):
        x = self.features(x)
        x = x.view(x.size(0), -1)
        x = self.fc(x)
        return x
Training loop

for sequences in train_sequences.split(batch_size):
    nb = sequences.size(0)

    # Select a random index in each sequence, this is our targets
    idx = torch.randint(len, (nb, 1), device = sequences.device)
    targets = sequences.gather(1, idx).view(-1)

    # Create masks and values accordingly
    tics = torch.arange(len, device = sequences.device).view(1, -1).expand(nb, -1)
    masks = (tics < idx.expand(-1, len)).float()
    values = (sequences.float() - mean) / std * masks

    # Make the input, set the mask and values as two channels
    input = torch.cat((masks.unsqueeze(1), values.unsqueeze(1)), 1)

    # Compute the loss and make the gradient step
    output = model(input)
    loss = cross_entropy(output, targets)

    optimizer.zero_grad()
    loss.backward()
    optimizer.step()
Synthesis

```python
nb = 25
generated = torch.zeros(nb, len, device = device, dtype = torch.int64)
tics = torch.arange(len, device = device).view(1, -1).expand(nb, -1)

for t in range(len):
    masks = (tics < t).float()
    values = (generated.float() - mean) / std * masks
    input = torch.cat((masks.unsqueeze(1), values.unsqueeze(1)), 1)
    output = model(input)
    dist = torch.distributions.categorical.Categorical(logits = output)
    generated[:, t] = dist.sample()
```
Some generated sequences
Image auto-regression
The exact same auto-regressive approach generalizes to any tensor shape, as long as a visiting order of the coefficients is provided.

For instance, for images, we can visit pixels in the “raster scan order” corresponding to the standard mapping in memory, top-to-bottom, left-to-right.

```python
image_masks = torch.empty(16, 1, 6, 6)
for k in range(image_masks.size(0)):
    sequence_mask = torch.arange(1 * 6 * 6) < k
    image_masks[k] = sequence_mask.float().view(1, 6, 6)
```

![Image Masks](image.png)
Some of the MNIST train images
We define two functions to serialize the image tensors into sequences

```python
def seq2tensor(s):
    return s.reshape(-1, 1, 28, 28)

def tensor2seq(s):
    return s.reshape(-1, 28 * 28)
```
Model

class LeNetMNIST(nn.Module):
    def __init__(self, nb_classes):
        super().__init__()

        self.features = nn.Sequential(  
            nn.Conv2d(2, 32, kernel_size = 3),
            nn.MaxPool2d(kernel_size = 2),
            nn.ReLU(),
            nn.Conv2d(32, 64, kernel_size = 5),
            nn.ReLU(),
        )

        self.fc = nn.Sequential(  
            nn.Linear(64 * 81, 512),
            nn.ReLU(),
            nn.Linear(512, nb_classes)
        )

    def forward(self, x):
        x = self.features(x)
        x = x.view(x.size(0), -1)
        x = self.fc(x)
        return x
Training loop

```python
for data in train_input.split(args.batch_size):
    # Make 1d sequences from the images
    sequences = tensor2seq(data)
    nb, len = sequences.size(0), sequences.size(1)

    # Select a random index in each sequence, this is our targets
    idx = torch.randint(len, (nb, 1), device = device)
    targets = sequences.gather(1, idx).view(-1)

    # Create masks and values accordingly
    tics = torch.arange(len, device = device).view(1, -1).expand(nb, -1)
    masks = seq2tensor((tics < idx.expand(-1, len)).float())
    values = (data.float() - mu) / std * masks

    # Make the input, set the mask and values as two channels
    input = torch.cat((masks, values), 1)

    # Compute the loss and make the gradient step
    output = model(input)
    loss = cross_entropy(output, targets)

    optimizer.zero_grad()
    loss.backward()
    optimizer.step()
```
Synthesis

```python
nb = 48
generated = torch.zeros((nb,) + train_input.shape[1:],
                        device = device, dtype = torch.int64)
sequences = tensor2seq(generated)
tics = torch.arange(sequences.size(1), device = device).view(1, -1).expand(nb, -1)

for t in range(sequences.size(1)):
    masks = seq2tensor((tics < t).float())
    values = (seq2tensor(sequences).float() - mu) / std * masks
    input = torch.cat((masks, values), 1)
    output = model(input)
    dist = torch.distributions.categorical.Categorical(logits = output)
    sequences[:, t] = dist.sample()
```
Some generated images
Masks, generated pixels so far, and posterior on the next pixel to generate (red dot), as predicted by the model (logscale). White is 0 and black is 255.
The same generative process can be used for in-painting, by starting the process with available pixel values.

Original Input Several synthesis
Some remarks:

- The index ordering for the sampling is a design decision. It can be fixed during train and test, or be adaptive.
Some remarks:

- The index ordering for the sampling is a design decision. It can be fixed during train and test, or be adaptive.

- Even when there is a clear metric structure on the value space, best results are obtained with cross-entropy over a discretization of it.

This is due in large part to the ability of categorical distributions and cross-entropy to deal with exotic posteriors, in particular multi-modal.

- Even when there is a clear metric structure on the value space, best results are obtained with cross-entropy over a discretization of it.

This is due in large part to the ability of categorical distributions and cross-entropy to deal with exotic posteriors, in particular multi-modal.

- The cross entropy for a sample is $\ell_n = -\log \hat{p}(y_n)$ hence $e^{\ell_n} = \frac{1}{\hat{p}(y_n)}$.

If the predicted posterior was uniform on $N$ values, this loss value would correspond to $N = e^{\ell_n}$. This is the perplexity and is often monitored as a more intuitive quantity.
The end
