## Deep learning

4.5. Pooling

François Fleuret https://fleuret.org/dlc/

The historical approach to compute a low-dimension signal (e.g. a few scores) from a high-dimension one (e.g. an image) was to use **pooling** operations.

Such an operation aims at grouping several activations into a single "more meaningful" one.

François Fleuret

Deep learning / 4.5. Pooling

The most standard type of pooling is the **max-pooling**, which computes max values over non-overlapping blocks.

For instance in 1d with a kernel of size 2:

The average pooling computes average values per block instead of max values.

François Fleuret

Deep learning / 4.5. Pooling

Pooling with a  $w \times h$  kernel. Contrary to convolution, pooling is applied independently on each channel. There are as many channels as output.

François Fleuret

Deep learning / 4.5. Pooling

Pooling provides invariance to any permutation inside one of the cell.

More practically, it provides a pseudo-invariance to deformations that result into local translations.

François Fleuret

Deep learning / 4.5. Pooling

takes as input a  $N \times C \times H \times W$  tensor, and a kernel size (h, w) or k interpreted as (k, k), applies the max-pooling on each channel of each sample separately, and produces (if the padding is 0) a  $N \times C \times \lfloor H/h \rfloor \times \lfloor W/w \rfloor$  output.

Similar functions implements 1d and 3d max-pooling, and average pooling.

François Fleuret

Deep learning / 4.5. Pooling

As for convolution, pooling operations can be modulated through their stride and padding.

While for convolution the default stride is 1, for pooling it is equal to the kernel size, but this not obligatory.

Default padding is zero.

François Fleuret

Deep learning / 4.5. Pooling

Wraps the max-pooling operation into a Module.

As for convolutions, the kernel size is either a pair (h, w) or a single value k interpreted as (k, k).
